

# Introduction to Python

## Lesson plan

<b>Subject/Course</b>	<b>Python Programming</b>
<b>Lesson Title</b>	<b>Introduction to python</b>

<b>Lesson Objectives</b>
What is history of Python , Version History of Python
Why you should learn Python?, Features of Python , Amazing facts
Where Python can be used? , Learning Path

# History of Python

- Python was conceived in the late 1980's by Guido van Rossum at centrum Wiskunde and Informatica in the Netherlands as a successor of the ABC language.
- He has been invariably worked as the lead developer, until 12 July 2018
- In jan 2019, active Python core developers elected a five member council to lead the project

# Version History

- Python 1.0     1994
- Python 2.0     2000
- Latest version
- Python 3.11     2022
- Python 3.12     2023
- Python 3.13     2024
- Name – Python
- Python developers aim for it to be fun to use, the name 'python' is a tribute to the British comedy group Monty Python

# Why you should learn Python ?

- Huge community Support
- Future is with AI
- Easy to learn and implement
- General purpose programming language

# Features of Python

- Highly Extensible
- Simple and straight forward syntax
- Multi Paradigm programming language
- Emphasis on code readability
- Dynamic typing automatic memory management
- Dynamic Binding
- Precise Coding
- For time critical Operations, python can use modules written in C language
- Introduction base block of code
- Large library
- Platform independent

## Amazing facts

- Ranked #1(TIOBE)
- Highest rise in rating 2007, 2010, 2018, 2020
- It reduces app development time by 1/6
- Large organizations that uses python are Google, Netflix, Dropbox, Youtube, Instagram, CERN, Microsoft, NASA, Amazon, facebook, Mozilla, etc.

# Where Python can be used?

- Developing websites
- Task automation
- Data Analysis
- Data visualization
- AI, ML,IOT
- Developing desktop applications
- Python can also be used in developing mobile applications, client side AJAX based applications.

# Learning Path

- Learn by doing Projects
- Absolute Beginner →core python →oops
  - Develop console app using some DB.
  - Develop GUI app
  - Develop Web application
  - Develop ML based app
  - Learn Devops

# **VARIABLES AND TYPES**

## Variables:-

- Variables are used to hold data during execution of the program.
- In C, C++, you need to declare variables. Only after declaration you can use them.

```
int a;
```

```
float b;
```

- C, C++ are statically typed languages

- Python is dynamically typed language.
- In python you don't declare variables. If there is a need of a variable you think of a name and start using it as a variable

### C/C++

- `int a;`    ? declaration
- `a++;`
- `print("%d" , a);`
- `a = 7;`

### Python

`a = 5`    ? Automatic declaration

-----

`a = 5`

`a = a + 5`

## Variable name:-

- Variable name is any combination of alphabet, digit and underscore.
- Variable name cannot start with digit.
- Variable names are case sensitive.
- Keywords cannot be used as variable names.

## Deleting variable:-

- `x = 5`
- `-----`
- `del x`

## Dynamic type:-

- Not only the value of a variable may change during program execution but the type as well.
- `x = 5` # type of x is int
- `x = 5.7` # type of x is float
- `x = True` # type of x is bool
- `x = "country"` # type of x is str

- a = 5
- a = 6
- a = 3.4

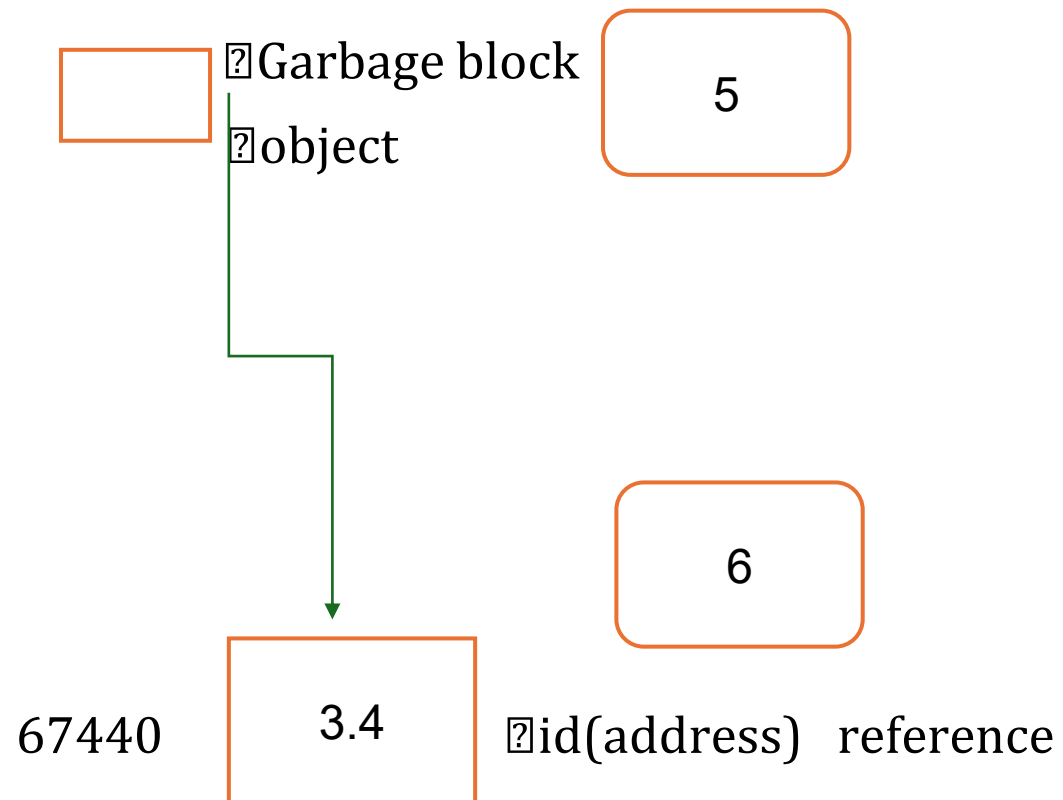

- int
- float
- bool
- str

data type  
Classes

- 

a

# Type()

- `type()` is a predefined function which returns the data type of a specified variable

- ```
x = 5  
type(x)  
x = 5.7  
type(x)
```

Data type is always a class in python

## Data types:-

### Numbers

```
int      5
float    3.7
complex  3+5j
```

### Boolean

```
bool     True
         False
```

### String

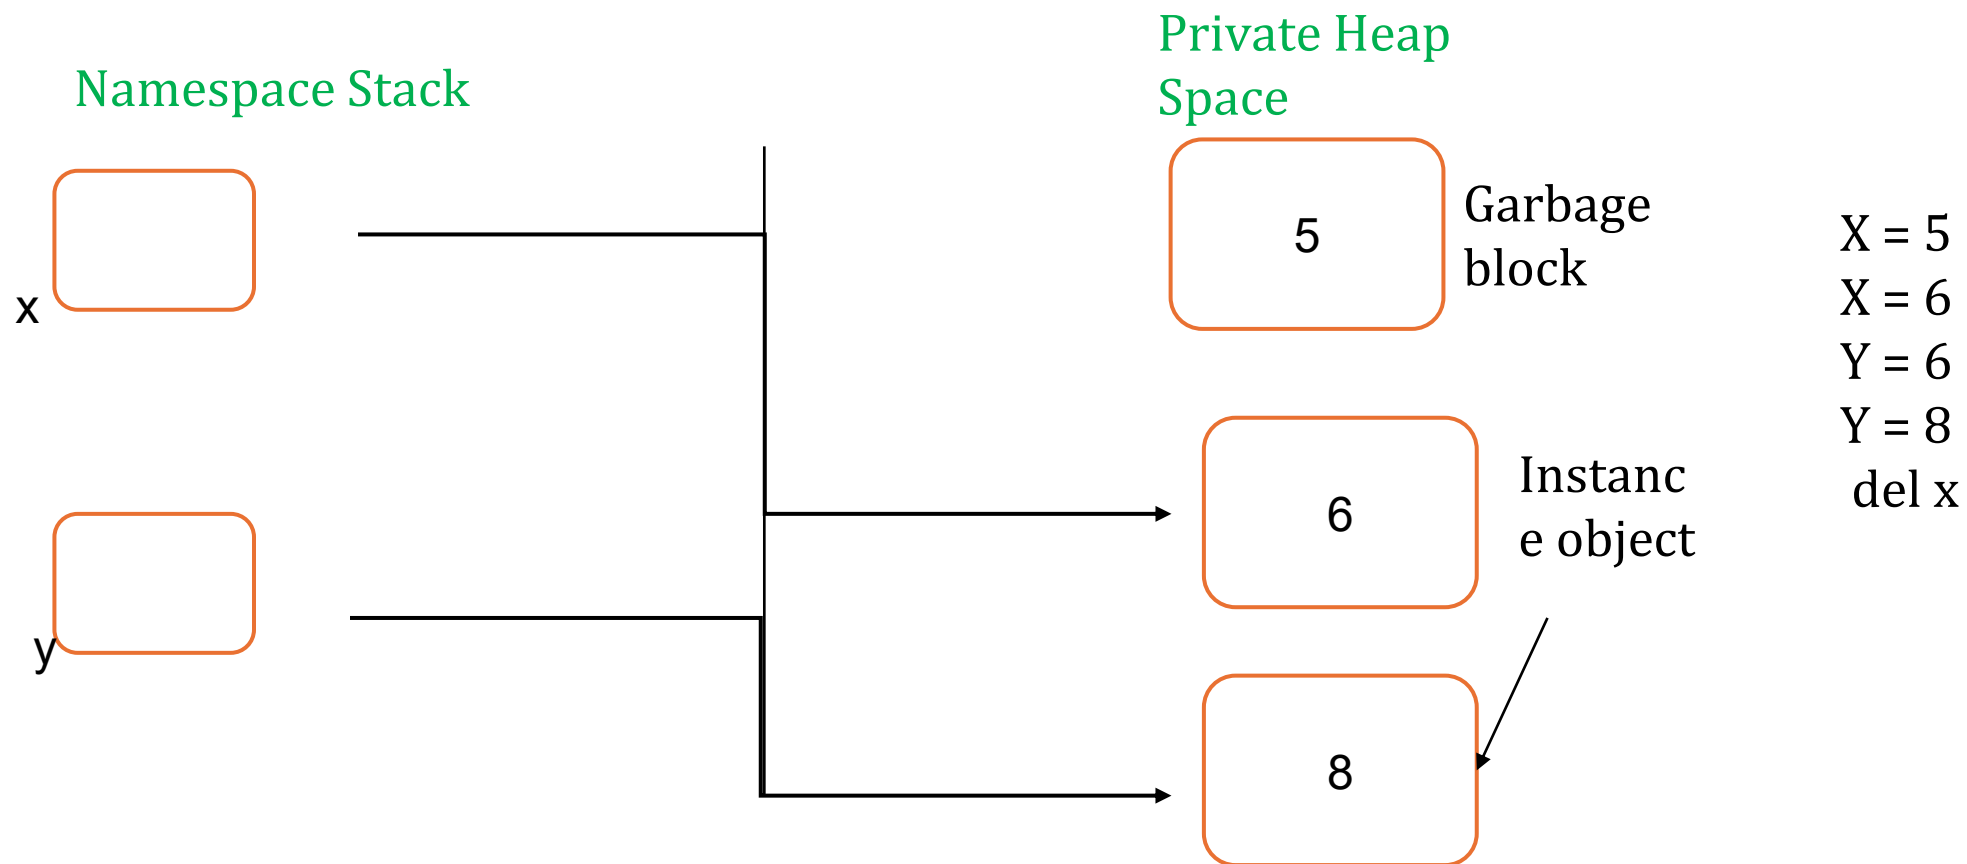

|     |           |               |
|-----|-----------|---------------|
| str | "college" | """college""" |
|     | 'college' | "'college'"   |

Double in not there in python

Char in not there in python

# Memory management

## Memory management:-

# Garbage Collection

- It is a program, invoked by python itself , whenever required, whose job is to release memory of garbage blocks  
(object which is not referenced by any name)
- Automatic memory management

# What is an object?

- Object is real world entity
- Object is an instance of a class
- Object is a proper noun
- Class is a common noun
- Doctor is a common noun class
- Dr . dixit is a proper noun object
- Dr . Sharma is a proper noun object

# Whose name?

- Name in namespace is a variable which is used to contain id(reference) of

1. Instance object
2. Function object
3. Class object

In python everything is an object.

**Print, keywords and import**

# Print()

- Print simple text `print("Welcome")`
- Print variable value `print(x)`
- Print expression `print(x+5*3)`
- Print multiple value `print(x , y)`

# Sep

```
a = 5
```

```
b = 6
```

```
c = 7
```

```
print(a , b, c)
```

- `print(a, b, c, sep = '_')`    5\_6\_7
- `print(a, b, c, sep = '#')`    5#6#7

# End

`a = 5`

- `b = 6`
- `print(a , b, c, end = ',')`
- `Print("Hello")`

# Special characters

## Escape Sequences

`'\n'` new line

`'\t'` tab space

`'\b'` backspace

`'\r'` Carriage Return

`'\\'` print \

`'\"'` print “

`'\''` print ‘

# Format Specifiers

- `x = 5`

`type(x)` `int`

value of x is 5

`print("value of x is" , x)`

value of x is 5

`print("value of x is %d" %(x))`

value of x is 5

# Module, Package and Library

**Module** : - It is a python file. It can contain instance objects, function objects and class objects.

In simple words, it contains variables, functions and classes

**Package**:- Package is a collection of modules and sub-packages

**Library**:- Library is a collection of packages.

# import

- Import A2  
`moduleName.moduleElement`
- ModuleElement can be
  - ▢ variable(instance object)
  - ▢ function
  - ▢ class

From A2 import x  
 Print(x)

A1.py

Module

A2.py

Module

- 

A1.py

```
From A2 import x as X
X = 10
Print(X) 5
Print(x) 10
```

A2.py

```
X = 5
```

# Keywords

- Predefined words
- Reserved words

|        |          |           |        |
|--------|----------|-----------|--------|
| False  | class    | from      | or     |
| None   | continue | global    | pass   |
| True   | def      | if        | raise  |
| and    | del      | import    | return |
| as     | elif     | in        | try    |
| assert | else     | is        | while  |

| -     | -   | -   | -    |

# Place Value

Decimal    2    1    4    8 = 2000 + 100 + 40 + 8

                  ↑    ↑    ↑    ↑

                  10<sup>3</sup> 10<sup>2</sup> 10<sup>1</sup> 10<sup>0</sup>

Octal            3145

Hexadecimal    A10F

Binary            1001110

# Conversion of Number System

Dec  $\rightarrow$  Bin

25  $\rightarrow$  11001

76  $\rightarrow$

100  $\rightarrow$

96  $\rightarrow$

## Number System Conversion functions

`x = 25`

`bin(x) → '0b11001'`

`oct(x) → '0o31'`

`hex(x) → '0x19'`

-----

`x = 0b11001`

`x = 0o31`

`x = 0x19`

# Unicode

The Unicode is character encoding, and its goal is to replace the existing character sets with its standard UTF.

UTF ☐ Unicode Transformation format

UTF -8 ☐ Is the most commonly used character encoding.

It is also backward compatible with ASCII

Character to Unicode

`x = 'A'`

`Ord(x) ☐ 65`

Unicode to character

`x = 65`

`chr(x) ☐ 'A'`

# Taking Input from user

`input()`

`input()` can take at most one argument of str type

`input()` always return str type value

How to input a string?

```
s = input()
```

How to input an int value?

```
x = int ( input())
```

How to input a float value?

```
x = float ( input())
```

How to input a complex value?

```
x = complex (input())
```

## Input can take one argument

- To provide direction for input you can pass a string argument in input method.

```
name = input("Enter your name")
```

```
age = int(input("Enter your age"))
```

## Can you take multiple value?

- You can use multiple input() function to input multiple values

```
a = int ( input ( "Enter first number"))
```

```
b = int ( input( "Enter second number"))
```

You can input multiple values using single input() function but it is little bit tricky and requires knowledge of str class, which we will see in later lessons.

# OPERATORS

|                              |                       |
|------------------------------|-----------------------|
| Bitwise OR                   | $a b$                 |
| Exponentiation               | $a**b$                |
| Identity                     | $a \text{ is } b$     |
| Identity                     | $a \text{ in not } b$ |
| Indexed Assignment           | $\text{obj}[i] = a$   |
| Indexed Deletion             | $\text{del obj}[i]$   |
| Indexing                     | $\text{obj}[i]$       |
| Left shift                   | $a<<b$                |
| Right shift                  | $a>>b$                |
| Logical AND                  | $a \text{ and } b$    |
| Logical OR                   | $a \text{ or } b$     |
| Modulo                       | $a\%b$                |
| Multiplication or Repetition | $a*b$                 |
| Negation                     | $-a$                  |

|                                    |                              |
|------------------------------------|------------------------------|
| Negation (logical)                 | <code>not a</code>           |
| Positive                           | <code>+a</code>              |
| Slice Assignment                   | <code>s[i:j] = values</code> |
| Slice Deletion                     | <code>del s[I : j]</code>    |
| Slicing                            | <code>s[I : j]</code>        |
| String formatting                  | <code>s%s1</code>            |
| Subtraction                        | <code>a - b</code>           |
| Ordering(less than)                | <code>a &lt; b</code>        |
| Ordering(greater than)             | <code>a &gt; b</code>        |
| Ordering(less than or equal to)    | <code>a &lt;= b</code>       |
| Ordering(greater than or equal to) | <code>a &gt;= b</code>       |
| Equality                           | <code>a==b</code>            |
| Not equal                          | <code>a !=b</code>           |

# Operators:-

- Arithmetic Operators      `**, /, //, *, %, +, -`
- Relational Operators      `<, >, <=, >=, ==, !=`
- Logical Operators      `not, and, or`
- Bitwise Operators      `&, |, ^, ~, >>, <<`
- Assignment Operators      `=, +=, -=, //=, %=, **=, *=, &=, |=`
- Identity Operators      `is, is not`
- Membership Operators      `in, not in`

`++, --` are not the operators in python

# Arithmetic Operators:-

**`**`, `//`, `/`, `*`, `+`, `-`, `%`**

`2**3`    `2*2*2` = 8

/ always return float result

// always return floor value , int type or float type depending on operands.

+, \* can be used with str type values also

- + is addition operator when operands are numbers (int, float, complex, bool)
- + is concatenation operator when operands are str
- + operation is invalid when applied between a number and a string.
- \* is used to multiply two numbers
- \* is repetition operator when applied between a str and an int

# Relational Operators

- `<`, `>`, `<=`, `>=` ? inequality operators
- `==`, `!=` ? equality operators ? never gives error

- Relational operators always give result in True or False.
- When truth value is converted to int, it becomes 1 for True and 0 for False
- Relational operators can also be used to compare two strings
- Only == and != operators can be used between two complex type values.
- == and != never yield error

# Logical operators

not

and

or

- Logical operators must be written in lowercase only

not True  $\Rightarrow$  False

not False  $\Rightarrow$  True

True and True  $\Rightarrow$  True

True and False  $\Rightarrow$  False

False and X  $\Rightarrow$  False

False or False  $\Rightarrow$  False

False or True  $\Rightarrow$  True

True or X  $\Rightarrow$  True

Every non zero value  $\neq$  True

Zero  $\neq$  False

Non empty string  $\neq$  True

Empty string  $\neq$  False

When operands are non-bool then result will also be non-bool

# Bitwise Operators

&, |, ^, !, >>, <<

0&0 = 0

0&1 = 0

1&0 = 0

1&1 = 1

---

0|0 = 0

0|1 = 1

1|0 = 1

How to assign values to multiple variables in a single line?

`x = 4, y = 3, z = 2`    **Error**

`x, y, y = 4, 3, 2`    **correct**

`x, y, z = 2, 3`    **Error**

# Identity Operator

is

is not

It checks whether the two references referring to the same object or no.

It results in True or False.

a = 3.5    a ?

x = 5

x ?

b = 3.5

y = 5

y ?

b ?

3.5

5

3.5

a = 5      a ? 5  
b = 5      b ? reference count (2)

# Membership operators

in

Not in

These operators are applicable only on containers (iterable)

They result True or False

Container is a type which can contain multiple values and also iterable

x

15, 20, 37, 4, 61

15 in x    True

25 in x    False

int, float, complex, bool are not iterable

str, range, list, tuple, set, dict are iterable

## **Decision control**

# Control statement

1. Decision control
  - if
  - if else
  - if elif else
  - single line if else
2. Match case
3. Iterative control

-----  
 -----

**if**

- Write a program to check whether a given number is positive or non positive

```
x = int ( input("Enter a number"))
```

```
if x>0:
```

```
    print("positive")
```

```
if x<=0:
```

```
    print("non positive")
```

# if else

- Write a program to check whether a given number is positive or non positive

```
x = int(input("Enter a number"))
```

```
if x>0:
```

```
    print("Positive")
```

```
else:
```

```
    print("Non positive")
```

# if elif else

if condition:

----- T  
-----

Elif condition:

----- T  
-----

Elif condition:

----- T  
-----

Else:

-----  
-----

elif = else if

Write a program to print grade obtained in a test. Take marks obtained from user and Display the grade.

90 < marks <= 100    A

80 < marks <= 90    B

70 < marks <= 80    C

60 < marks <= 70    D

50 < marks <= 60    E

below 50              F

# Single line if else

code1 if condition else code2

Single line if else is an expression but if else is not an expression

x = if ---:                      x = code1 if condition else code2

----

x = code1

----

Else:

-----

-----

Write a python program to check whether a given number is positive or non positive.

```
x = int (input("Enter a number"))  
print("positive") if x>0 else print("non positive")
```

# Nested if else

```
if condition:
```

```
    -----
```

```
    -----
```

```
        if condition:
```

```
            -----
```

```
            -----
```

```
        else:
```

```
            -----
```

```
            -----
```

```
else:
```

```
    -----
```

```
    -----
```

**Match, while loop, transfer control statement, and for loop**

```
match subject_expression:
```

```
    case constant:
```

```
        -----
```

```
    case constant:
```

```
        -----
```

```
    case constant:
```

```
        -----
```

```
    case constant:
```

```
        -----
```

break keyword cannot be used in match block

## Example:-

```
x = int(input("Enter a number"))
```

```
match x:
```

```
case 1:
```

```
    print("One")
```

```
case 2:
```

```
    print("Two")
```

```
case 3:
```

```
    print("Three")
```

```
case 4:
```

```
    print("Four")
```

case constant can be of any type.

```
x = eval(input("Enter a number"))
```

```
match x:
```

```
    case 1.1:
```

```
        print("One")
```

```
    case "two":
```

```
        print("Two")
```

```
    case True:
```

```
        print("Three")
```

## Default matching

```
x = int( input("Enter a number"))  
match x:  
    case 1:  
        print("One")  
    case 2:  
        print("Two")  
    case 3:  
        print("Three")  
    case _:  
        print("default")
```

# match

- match and case are soft keywords
- They are not reserved words in other grammatical contexts.
- They are recognized as keywords when part of a match statement or case block only, and are allowed to be used in all other contexts as variables or argument names.

## **duplicate case**

duplicate case is not an error but first match will only work.

# Conditional casing

match expression:

case data if condition:

-----

-----

case data if condition:

-----

-----

# While loop

## Objectives:-

1. Iterative control
2. while
3. practice problem

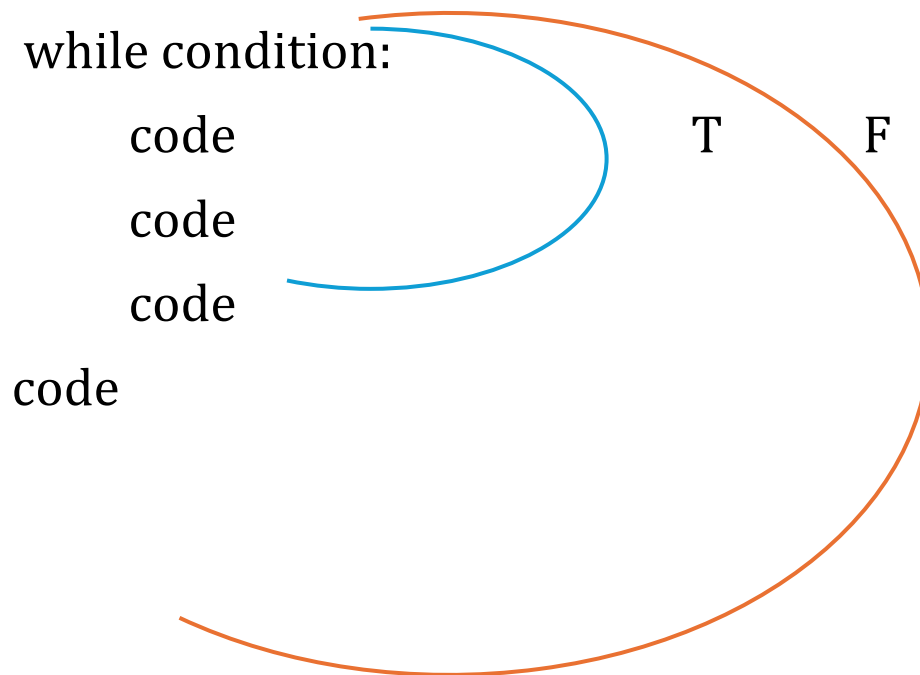

# Iterative control(Loop)

while

for

X do while

# while

- Write a program to print Hello Nature five times.

i=1 ? initialization

while i <=5: ?condition

print("Hello Nature")

i + = 1 ? flow

- Write a program to print first 10 natural numbers.

1 Read/understand

2. Test case

3. Dry run

- Write a program to print first 10 natural numbers in reverse order.

- Write a program to print first n even natural numbers.

## **Transfer control statement**

## Objectives:-

1. Break
2. continue
3. else with loop
4. pass

# break

- break is a keyword
- break is used to transfer control outside the loop body.
- break can only be used in the body of loop.
- break terminates the execution of loop.

- Write a program to ask user to enter an even number at most 3 times.  
It user failed to enter an even number in all the three chances then he has lost the game. If user enters an even number, then no more chances will be given and announced him a winner.

# **continue**

- Continue is a keyword
- It can only be used in the body of loop
- Continue transfer the control immediately to the next iteration.

# Example

- `i = 1`  
    `while i <= 10:`  
        `x = int (input("Enter a number"))`  
        `if x % 2 == 0:`  
            `continue`  
        `print(i ,"x = ", x)`  
        `I +=1`

## else with while loop

```
while condition:
```

```
    code
```

```
    code
```

```
else:
```

```
    code
```

else block executes when while loop terminates normally.

else block won't be execute when loop terminator due to break statement.

# pass

pass keyword is used to create empty block.

if condition:

pass

while condition:

pass

while(--)

{

}

if(---)

{

}

# For loop

## Objectives:-

1. for loop
2. practice program
3. for vs while
4. break in for
5. for else

# for loop

for loop only works on iterables.

```
for variable in Iterable:
```

```
    code
```

```
    code
```

Example

```
for x in "Hello":
```

```
    print(x)
```

output

H

e

l

l

o

Write a program to count 'a' in a given string, using for loop.

```
s = input("Enter a string")
    count = 0
for e in s:
    if e == 'a':
        count+= 1
print("Total occurrence of 'a' is" , count)
```

## while vs for

While loop iterates a block of code till the specified condition is true.

for loop iterates a block of code number of times same as number of elements in the iterable.

It iterates for elements of iterable from first element to the last element

# Iterable object

- Group of values
- Ability to access elements of the object ( from first element to the last element) is applicable on certain types.

## **break in for**

break keyword can be used only in the body of loop (while or for) break transfers the control outside the loop body and loop terminates

## for else

```
for variable in iterable:
```

```
    code
```

```
    code
```

```
    if condition:
```

```
        break
```

```
    code
```

```
else:
```

```
    code
```

```
    code
```

print all the character of a string, but stop printing it 'r' appeared in the sequence It all the character successfully prmted the print message "All the characters are processed"

```
x = input("Enter a string")
for i in x:
    if i == 'r':
        break
    print(i , end = "")
else:
    print("All the characters are processed")
```

# Range

# What are iterables?

- An iterable object is something that contains a countable number of values.
- You can traverse through all the values from beginning to the end.
- Technically, in Python, an iterator is an object, which implements the iterator protocol, which consist of methos `__iter__()` and `__next__()`

# Various iterables

- range
- list
- tuple
- str
- bytes
- bytearray
- set
- frozenset
- dict

# range

- range is a class
- range is immutable sequence
- range can contain only int type values
- range contains sequence of integers with common difference (Arithmetic progression)
- range elements are indexed

## How to create range object?

- `r = range (beg, end, step)`
- Example:-

`range (1 , 10 , 1)`

inclu exclu common gap

`range (2 , 8 , 2)` 2 4 6

`range (10 , 3 , -2)` 10 8 6 4

## Other ways to create range object

- `r = range (beg , end , syep)`
- `1 range(end)` beg = 0 step = 1
- `2 range( beg , end)` step = 1

# indexing

- `r = range(1, 6, 1)`

- 

`r[0] = 1`

`r[1] = 2`

`r[4] = 5`

positive and negative indexing

`r[-1] = 5` , `r[-2] = 4` , `r[-4] = 2`

## Accessing range elements

for e in r:

code

# e is an element of range

- Write a program to print first n natural numbers.

[use range and for]

```
n = 6
```

```
1 2 3 4 5 6
```

```
range(1 , n+1, 1)
```

- Write a program to print squares of first n natural numbers.  
[use range and for]

- Write a program to print first n even natural numbers in reverse order. [\[use range and for\]](#)

- Write a program to calculate sum of first n multiples of x.  
[use range and for]

# List

# list

list is a class

list is an iterable sequence

list is mutable

list is growable

list can store heterogeneous data

list elements are indexed

## How to create list object?

```
l1 = [10 , 20 , 30]          # Square brackets are used  
                             to denote a list
```

```
l2 = []          #empty list object
```

```
l3 = [50 , 3.5 , "abc"]  # Hetrogeneous elements
```

## How to access list elements?

```
l1 = [50 , 20 , 80 , 10 , 60 , 40]
```

```
print(l1) # [ 50 , 20 , 80 , 10 , 60 , 40]
```

```
print(l1[0]) #50
```

```
print(l1[1] , l1[2]) #20 80
```

0            1            2            3            4            5

|    |    |    |    |    |    |
|----|----|----|----|----|----|
| 50 | 20 | 80 | 10 | 60 | 40 |
|----|----|----|----|----|----|

## Concept of negative indexing

l1 = [50 , 20 , 80 , 10 , 60 , 40]

|    |    |    |    |    |    |
|----|----|----|----|----|----|
| -6 | -5 | -4 | -3 | -2 | -1 |
| 0  | 1  | 2  | 3  | 4  | 5  |

|    |    |    |    |    |    |
|----|----|----|----|----|----|
| 50 | 20 | 80 | 10 | 60 | 40 |
|----|----|----|----|----|----|

`print(l1[-1])` # 40

`print(l1[-2])` # 60

## Accessing list elements via for loop

```
l1 = [50 , 20 , 80 , 10 , 60 , 40]
```

```
for x in l1:
```

```
    print(x , end = ' ')
```

```
    i = 0
```

```
    while i<=5:
```

```
        print(l1[i],end = ' ')
```

```
        i+=1
```

## How to delete an element from the list?

L1 = [50 , 20 , 80 , 10 , 60 , 40]

del l1[2]

## How to edit an element of the list?

`l1 = [50 , 20 , 80 , 10 , 60 , 40]`

|  |  |  |  |  |  |
|--|--|--|--|--|--|
|  |  |  |  |  |  |
|--|--|--|--|--|--|

`l1[2] = 45`

|  |  |  |  |  |  |
|--|--|--|--|--|--|
|  |  |  |  |  |  |
|--|--|--|--|--|--|

## How to add more elements in the list?

```
l1 = [50 , 20 , 80 , 10 , 60 , 40]
```

```
l1[6] = 70    # index error
```

```
list object[invalid Index]    is an error
```

```
l1[5] = 70
```

```
l1[4] = 90
```

Not adding more values in the list but only updating values at index 5 and 4

There are two standard ways to add elements in the list:

1 append()  
2 insert()

} attributes of list class

Class is a group of variables and functions

There variables and function are called attributes.

- `listObject.append(value)`
- `listObject.insert(index, value)`

append method adds value at the end of the list, that is new element will become the last element of the list

```
l1 = [50, 20, 80, 10, 60, 40]
```

```
l1.append(70)
```

`l1 = [50 , 20 , 80 , 10 , 60 , 40]`

`l1.insert(-5 , 70)`

`l1.insert(index , value)`

If index > last index then value will store at last index+1 only(append)

# Packing and Unpacking

```
l1 = [20 , 50 , 30]
```

```
a , b , c = l1          # unpacking
```

number of variables in the left hand side must be same as the number of elements in the list.

```
a = 5
```

```
b = 6
```

```
c = 10
```

```
l2 = [a , b , c]       # packing
```

## Built in methods

`len()` ? return length of specified iterable

`min()` ? return min value element

`max()` ? returns max value element

`sum()` ? returns sum of elements.

`sorted()` ? returns a sorted list of elements

`l = [24, 13, 5]`

`l1 = sorted(l)`

`[5, 13, 24]`

## list() method

```
l1 = list()      # l1 = []
```

```
l1 = list(10)    # l1 = [10]    error
```

```
l1 = list(10 , 20 , 30)
```

```
l1 = list("MySirG")
```

```
l1 = list(range(5))
```

```
l1 = list([10 , 20])
```

list() method can take at most one argument.

one argument ? **iterable**

## Comparison Operator on list

`l1 = [1, 2, 3]`

`l2 = [2, 3, 1]`

`l3 = [1, 2, 3, 4, 5]`

`l4 = [1, 2, 3]`

`l1 == l2` False

`l1 == l3` False

`l1 == l4` True

`l1 > l2` False

# Concatenation Operator

l1 = [1 , 5 , 9]

l2 = [2 , 3 , 1]

l3 = l1 + l2

|  |  |  |
|--|--|--|
|  |  |  |
|--|--|--|

|  |  |  |
|--|--|--|
|  |  |  |
|--|--|--|

l1 + = l2 ? **l1 = l1 + l2**

|  |  |  |  |  |  |
|--|--|--|--|--|--|
|  |  |  |  |  |  |
|--|--|--|--|--|--|

## Repetition Operator

$$l1 = [2, 5]$$

|  |  |
|--|--|
|  |  |
|--|--|

11 \* 5

[illegible]

# Slicing Operator

`listObject[beg : end : step]`

`l1 = [20 , 40 , 10 , 30 , 60 , 50]`

By default step = 1

By default beg ,and = extreme end

`l1[2 :6 :2]`

`l1[4 : 0 :-1]`

# **Str , sets , tuples and dictionaries**

# Str

str is a class

str is immutable

str is iterable

str is hashable

str is a sequence

## How to create str object?

```
s1 = "college"
```

```
s2 = 'college'
```

```
s3 = """Hello"""
```

```
s4 = ""Hello""
```

```
s5 = str()
```

```
s6 = str(125)
```

```
s7 = str(3.45)
```

# indexing

s1 = "College"

s1[0]    C

s1[2]    l

|   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|
| C | o | l | l | e | g | e |
|---|---|---|---|---|---|---|

## Accessing str elements

1. `s1[index]`
2. `print(s1)`
3. for loop
4. slicing operator                      `strobj[ :: ]`

## Built in methods

`len()`

`min()`

`max()`

`sum()`

`sorted()`

# Concatenation and repetition operator

|           |                     |                  |
|-----------|---------------------|------------------|
| $s1 + s2$ | $s1 = \text{"ABC"}$ | $s1 + s2$        |
|           | $s2 = \text{"DE"}$  | $\text{"ABCDE"}$ |

|          |          |                   |
|----------|----------|-------------------|
| $s1 * 3$ | $s2 * 3$ | $\text{"DEDEDE"}$ |
|----------|----------|-------------------|

# Comparison Operator

$s1 > s2$  ? true if  $s1$  comes after  $s2$  in dictionary order

## Str object methods

index()

count()

startswith()

endswith()

split()

join()

format()

isdigit()

islower()

isupper()

lower()

upper()

replace()

# split

```
s1 = " education services"
```

```
l1 = s1.split( ' ' )
```

split function returns a list of splitted strings

```
l1 = ["education" , "services"]
```

# join()

```
l1 = ["education", "services"]
```

```
space = " "
```

```
s2 = space.join(l1)
```

join will return a string which is formed by joining elements of l1 with the help of spaces.

# format

```
String.format(var1 , var2 , ....)
```

```
print(" { } , how are you?" .format("Mahavir"))
```

```
print(" { } , { } , { } " .format(one" , 25 , 3.5))
```

```
print(" {2} , {0} , {1}" .format(10 , 20 , 30))
```

## Split and join

```
s1 = " education services"
```

```
l1 = s1.split(" ")
```

split function returns a list of splitted strings

```
l1 = ["college", "education", "services"]
```

## Taking input list elements

```
s1 = "35 , 40 , 20 , 10 , 55 , 80 ,17 , 60"
```

```
l1 = s1.split(',')
```

```
l1 = ["35" , "40" , "20" , "55" , "80" , "17" , "60"]
```

```
mylist = [int(e) for e in l1]
```

```
    = [35 , 40 , 20 , 10 , 55 , 80 ,17 ,60]
```

## join()

`l1 = ["25", "10", "2025"]`      list of str

list of str → str

"25102025"

"25/10/2025"

"25-10-2025"

`s1 = "-".join(l1)`

join returns a str type value

split ? str ? list of str                      base string  
 join ? list of str ? str                      base string

```
S1 = 'Education Services'
base string = ' ' (space)
s1.split(' ') ? ['Education', 'Services']
l1 = ['Education', 'Services']
base string = ' ' (space)
baseString.join(list of str)
' '.join(l1) ? 'Education Services'
```

# set

set is a class

set is mutable

set is not hashable

set is iterable

set is not a sequence

set cannot have duplicate values

indexing is not applicable to set object

Slicing operator is not applicable

set does not guarantee to store values in the order of insertion

## How to create set object?

```
s1 = { 1 , 5 , 8 }
```

```
s2 = { 10 , 2 , 8 , 10 , 10 , 8 }
```

```
s3 = { }
```

```
s4 = set()
```

```
s5 = set([1 , 5 , 3])
```

Elements of set object must be hashable

## Accessing set elements

```
for e in setobject:  
    code
```

## built – in methods

len()

min()

max()

sum()

sorted()

# Concatenation and Repetition Operator

|           |               |
|-----------|---------------|
| set + set | not supported |
| set * int | not supported |

## Comparison operator

`s1 > s2`

`s1 > s2`

`s1 >= s2`

`s1 <= s2`

`s1 == s2`

`s1 != s2`

Two set objects are equal if their elements are same , doesn't matter the order of elements.

## set object methods

add() add specified item in a set  
update() add iterable(s) elements  
discard() remove item  
remove()  
intersection()  
union()  
clear()  
is subset()  
Is superset()  
pop()

## set comprehension

```
s1 = { expression for e in object }
```

```
s = input ("Enter a string")
```

```
s1 = { e for e in s if e in "aeiou" }
```

```
    for e in s:
```

```
        if e in "aeiou":
```

```
            s1.add(e)
```

## user input

```
s = input("Enter elements separated by comma")  
s1 = { eval(e) for e in s.split(',') }
```

## **frozenset**

A set is a mutable object while frozenset provides an immutable implementation.

# tuple

tuple is a class

tuple is iterable

tuple is immutable

tuple is a sequence

## How to create tuple object?

t1 = (1 , 2 , 5 , 7)

t2 = ()

t3 = (10)    ❌ not a tuple

t3 = (10 ,)

t4 = 10 , 20 , 30

# indexing

$t1 = (10, 20, 30)$

|  |  |  |
|--|--|--|
|  |  |  |
|--|--|--|

## Accessing tuple elements

```
t1 = (10 , 5 , 20 , 15)
```

1. `t1[0]`

```
    printf(t1[1])    5
```

2. `i = 0`

```
    while(i<len(t1))
```

```
        print(t1[i])
```

```
        i+=1
```

3. For a in t1:

```
    print(a)
```

## built – in methods

len()

min()

max()

sum()

sorted()

# Concatenation and Repetition Operator

$t1 = (10, 20)$

$t2 = (11, 22, 33)$

$t1 + t2$                        $(10, 20, 11, 22, 33)$

$t1 * 3$

# Comparison Operator

t1 = (10 , 20)

t2 = (11 , 33 , 55)

t1 > t2    false

t1 == t2   false

t2 > t1    True

## **tuple object methods**

`index()`

`count()`

# Slicing operator

`t1[beg : end : step]`

`t1[::-1]`    reverse

## user input

```
t1 = tuple([int(e) for e in input().split(',')])
```

```
t1 = tuple()
```

```
t2 = tuple([1, 2, 3])
```

```
t3 = tuple(range(range(5)))
```

# dict

- dict is a class
- dict is mutable
- dict is not hashable
- dict is iterable
- dict is not a sequence
- dict cannot have duplicate keys (not data values)
- indexing is not applicable to dict object
- slicing operator is not applicable
- dict elements are pair of key-value and data-value

## How to create dict object?

| Rollno | Student name |
|--------|--------------|
|--------|--------------|

|     |         |
|-----|---------|
| 102 | "Rahul" |
|-----|---------|

|     |         |
|-----|---------|
| 105 | "Payal" |
|-----|---------|

|     |          |
|-----|----------|
| 106 | "Prachi" |
|-----|----------|

```
d1 = { 102: 'Rahul' , 105 : 'Payal' , 106 : 'Prachi'}
```

```
d1 = {}      #empty object
```

| d1 = dict (a = 10 , b = 20 , c = 30) | key | data |
|--------------------------------------|-----|------|
|                                      | 'a' | 10   |
|                                      | 'b' | 20   |
|                                      | 'c' | 30   |

## Accessing dict elements

```
d1 = {102 : 'Rahul' , 105 : 'Payal' 106 : 'Prachi'}
```

1. `print(d1)`
2. `print(d1[102] , d1[105] , d1[106])`
3. `for k in d1:`  
    `print(k)`      ☐ only keys
4. `For k in d1:`  
    `print(k , d1[k])`

## How to edit dict element?

Editing dict element means you want to change data – value of the element and not the key – value

```
dict Object [key – vaule] = new data value
```

```
del d1[102]
```

## How to add new element in the dict?

```
dictObject [ new – key – value] = data – value
```

## methods

`items()` → collection dict elements

`keys()` → collection of keys only of the elements

`values()` → collection of data-values only of the dict elements

All these methods are dict class attributes

## **built – in methods**

len()

min()

max()

sum()

sorted()

# Concatenation and Repetition Operator

|             |               |
|-------------|---------------|
| dict + dict | not supported |
|-------------|---------------|

|            |               |
|------------|---------------|
| dict * int | not supported |
|------------|---------------|

# Comparison Operator

`d1 > d2`

`d1 >= d2`

`d1 < d2`

`d1 <= d2`

`d1 == d2`

`d1 != d2`

Two dict object are equal if their items are equal.

Elements can be stored in any order.

## **dict object methods**

`pop(key)`

`popitem()`

`clear()`

## dict comprehension

`d1 = { key- expression: data-expression for v in seq }`

**Thank you!**
